Casting stainless steel with magnesium-alloy chips

in one direction); in the second version the lower part was machined as in the first variant, but the other parts were also roughened to 2 - 4 mm. Roughing according to variant 1 decreased the metal losses from 6% to 1.0 - 1.5%, while the output was raised 1.5 - 2 times. As, on account of technological shortcomings, there may be surface defects on the upper part of the ingots, a combined finishing method is now applied: if there are scattered defects in the middle and the upper part of the ingots, not deeper than 2 mm, they are roughened according to variant 1. If defects appear in the lower part of the ingot, 4 mm deep, this part will also be roughened according to variant 1, while defects in the middle and upper part are being removed by grinding. If the middle and upper parts of the ingot show many defects, caused by faulty technology, the ingots have to be roughened according to variant 2. This combined finishing method greatly reduced metal losses, which usually occur in roughing. Similar results were obtained with 2.8-ton ingots of 35 X H 4 (35KhYuA) steel. To reduce defects in macrostructure, widened nozzles were applied and the amount of lunerite filled in the riser was increased from 1.5 to 3 kg/ton. The flashing and spattering of magnesium is not dangerous for the workers.

TITLE: Main technical characteristics of the "Tokamak-3" experi-  
mental thermonuclear installation

SOURCE: Atomnaya energiya, v. 17, no. 4, 1964, 287-294

TOPIC TAGS: thermonuclear pinch, thermonuclear fusion, plasma re-  
search, plasma pinch/Tokamak-3

ABSTRACT: The "Tokamak-3" is intended for the investigation of a  
toroidal quasi-stationary discharge in the strong longitudinal mag-  
netic field. The toroidal discharge is produced in the vacuum cham-

Card 1/3

i 13271-05

ACCESSION NR: AP4047415

ber by a vortical electric field, and acts as an equivalent secondary turn of a pulse transformer. The produced plasma pinch is stabilized with a longitudinal magnetic field of a toroidal solenoid, inside which the vacuum chamber is located. The magnetic core of the pulse transformer carries the primary vortical-field winding, the demagnetization winding, and the winding for induction heating. The set-up is fed from special power systems. The electromagnetic system, the power supply, and the vacuum system are described in some detail. The longitudinal field intensity reaches 40 kG. The vortical field values are 250 and 50 V per turn with pulse durations 10 and 50 milliseconds, and with programming of the waveform such as to maintain a constant current in the plasma pinch. The power supply delivers a peak power of 77,000 kW, maximum 7000 A, no-load voltage 11 kV, and stored energy 180 million Joules. The vortical field is fed from four capacitor banks rated 1000  $\mu\text{F}$  at 20 kV, 11,000  $\mu\text{F}$  at 10 kV, 78,000  $\mu\text{F}$  at 5 kV, and 30,000  $\mu\text{F}$  at 5 kV. The capacitor-bank parameters can be varied over a wide range. The vacuum in the liner does

PERIODICAL: V sb.: Prom. primeneniye tokov vysokoy chastoty. Riga, 1957,  
pp 84-90

ABSTRACT: A calculation of the power required to fuse and heat Si from the cold state and a method for the choice of inductor dimensions are presented. It is found that to maintain a zone 1 cm thick in the fused condition in a Si bar 1 cm in diameter ~ 400 w power is required. It is observed that an increase in inductor diameter causes a more uniform current distribution in the rod and an increase in the width of the zone of heating, while change in inductor height has little influence upon the current distribution in the Si rod. When the inductor is 2 cm in diameter and the rod is 1 cm, the minimum frequency required to heat the Si ranges from ~ 2 mc at a resistivity of 1 ohm·cm to ~ 100 mc at 500 ohm·cm.

TITLE: Heat problems in zonal melting without crucibles

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 4, 1962, 46 - 47, abstract 40315 (V sb. "Prom. primeneniye tokov vysokoy chastoty v elektrotermii", Moscow-Leningrad, Mashgiz, 1961, 124 - 129)

TEXT: The authors calculated the power necessary to produce the molten zone, assuming that this power is dissipated from the surface of the melt and the sections of the solid rod located near the zone. The total power is equal to

$$P = \pi D (\sigma HT_0^4 + \sqrt{2 \sigma \lambda DT_0^5 / 5}), \tag{1}$$

where D is the rod diameter, T is the absolute surface temperature,  $\sigma$  is the emissivity of the material,  $\lambda$  is the coefficient of heat conductivity. The superposition of displacement rate of the zone,  $v$ , entails some modification of the basic equation. For zonal melting of Si with  $D = 3$  cm, a calculation is presented which shows that in this case additional power  $\Delta P$  is consumed. At  $v = 1, 3$

TITLE: A high frequency induction discharge in a chamber with metallic water-cooled walls

SOURCE: Teplofizika vysokikh temperatur, v.3, no.6, 1965, 922-923

TOPIC TAGS: plasma generator, high frequency discharge, magnetic field

ABSTRACT: A new design makes possible the reliable creation of an induction discharge, without electrodes, with a power of tens of kilowatts at pressures from 10-2 mm Hg up to atmospheric pressure. If a hollow metallic cylinder is placed inside the inductor, and the wall thickness of the cylinder is much greater than the depth of penetration of the electromagnetic field into the metal, then the field inside the cylinder will practically be equal to zero. However, if a slot is cut in the cylinder, the electromagnetic energy will penetrate freely to the inside and an induction discharge can be created there. The induction discharge inside the cylinder is in the form of an annular induction current. The optimum number of slots was found to be from 8 to 10. The article shows

Cord 1/2

UDC: 533.9.07

L 11899-66

ACC NR: AP6001916

a schematic of the equipment. A quartz or glass tube is inserted to prevent the flow of cold or hot gas through the slots. Measurements were made of the absolute intensity of the recombined argon continuum in the region of 4300-4700 Å, where the intensity depends only slightly on the wave length. In the tests, the flow rate of argon through the discharge was approximately 30 liters/min, the frequency of the generator was 17 megacycles, and the power of the discharge was approximately 4.5 kilowatts. A photograph shows an operating high frequency plasma burner with a water-cooled metallic chamber. In this case, the power of the burner was 7 kilowatts, the pressure was atmospheric, and the consumption of argon was 60 liters/min. Orig. art. has: 3 figures.

TITLE: High-frequency inductor for metal welding. Class 21, No. 176645 39  
B

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 23, 1965, 36

TOPIC TAGS: metal, ~~active~~ metal welding, ~~metal~~ welding, high frequency welding, ~~welding inductor, high frequency inductor~~ *welding technology*

ABSTRACT: This Author Certificate introduces an inductor for metal welding with high-frequency currents. ~~The inductor, which is made from electroconductive material, is put on the part to be welded. It has channels for cooling water and for shielding gas which is fed to the welding zone. For welding chemically active metals, the inductor is insulated inside with a thin layer of heat-resistant material making it possible to enclose tightly the welded parts in the inductor. A variant of the above inductor has been designed for welding complex-shaped parts. In this case the inductor is provided with a collar coated inside with a thin heat-resistant layer, with which the inductor is put on the welded part, and a housing, which envelops this collar.~~ *(ND)*

TITLE: Stability of Unfired Magnesite-Chromite Bricks in Roofs of Open Hearth Furnaces (Stoykost' bezobzhigovogo magnezitokhromitovogo kirpicha v svodakh martenovskikh pechey)

PERIODICAL: Stal', 1958, Nr 4, pp 317-319 (USSR)

ABSTRACT: For the last two years open hearth roofs in the Vyksa Works were made either completely or partly from unfired magnesite-chromite bricks. Some data on the stability of roofs on the works is given in Table 1. The external appearance of unfired bricks after 581 and 623 heats is shown in Fig.1. Chemical composition of fired and unfired bricks from various zones of the roof after 380 heats - Tables 2 and 3. On the basis of the operational results the following conclusions are drawn: the stability of unfired magnesite-chromite bricks in roofs of 60 and 180 ton open hearth furnaces is 15 to 20% lower than that of fired bricks. In mixed roofs made from fired bricks at the front and back walls and unfired bricks in the middle part of the roof, their stability increases and stresses in roofs decrease due to the

Card 1/2

Stability of Unfired Magnesite-Chromite Bricks in Roofs of Open  
Hearth Furnaces 133-58-4-10/40

shrinkage of unfired bricks and the expansion of fired bricks on heating the furnace. In view of the comparatively low cost of unfired bricks, wider tests of their application in roofs of open hearth furnaces of various capacities should be made. There are 3 tables and 5 figures.

2218. Polarographic determination of base-metal impurities in platinum. <sup>7</sup> Ab. A. Muromtsev and V. D. Ratnikov. *Izv. Sborna Plating, I.O.N.K.A., Akad. Nauk, SSSR*, 1965, (32), 52-58; *Ref. Zhur., Khim.*, 1966, Abstr. No. 47,341.—The polarographic determination of Fe, Ni, Pb, Cu and Te in platinum is carried out by dissolving the sample in aqua regia, evaporating three times with conc. HCl, dissolving the dry residue in 2% HCl, and removing Pt from these base metals by a previously described method of reduction with HgCl (Karpov and Fedorova, *Izv. Inst. Plating, Akad. Nauk, SSSR*, 1935, 12, 103). The HgCl<sub>2</sub> formed in the reduction is converted into mercury chloramide by the action of NH<sub>3</sub>, and is removed by ignition. Dissolve the dry residue in a known vol. of dil. HCl and determine Pb in an aliquot on a background of 0.5 M K Na tartrate. In another aliquot, remove Fe by two pptn. with aq. NH<sub>3</sub>, and determine Cu and Ni on a background of M aq. NH<sub>3</sub> and 0.2 N NH<sub>4</sub>Cl. Dissolve the Fe(OH)<sub>3</sub> in hot dil. HCl, add a crystal of ammonium oxalate, evaporate till HCl is removed, dissolve the residue in a saturated soln. of ammonium oxalate or M K oxalate and subject to polarography. The polarograms are taken as follows— for Cu and Ni from -0.2 to -1.4 V; for Fe from 0 to -0.6 V; for Pb from -0.3 to -0.9 V. Determine Te in a separate sample by mixing with finely divided NaCl and active carbon and chlorinating for 5 hr. at 700°. The sublimed Te is trapped in 50% HCl and separated as elementary Te by the action of SO<sub>2</sub> and hydrazine. Evaporate and ignite to remove the H<sub>2</sub>SO<sub>4</sub> formed, oxidize Te in the residue with conc. HNO<sub>3</sub>, and again evaporate to dryness. Dissolve the residue, and obtain a polarogram in a solution of 0.3 M aq. NH<sub>3</sub>, with 0.1 N NH<sub>4</sub>Cl, or M NaOH, from -0.5 to -1.1 V.

TITLE: The effect of certain cycle parameters on the efficiency of a nuclear gas turbine plant

SOURCE: Atomnaya energiya, v. 20, no. 5, 1966, 412-415

TOPIC TAGS: gas turbine, gas cooled nuclear reactor, regenerative cooling

ABSTRACT: The results of an investigation of the effect of the turbine inlet temperature, gas pressure, compression ratio, and regeneration and intermediate cooling and heating of gas on the internal efficiency of a nuclear gas turbine plant with respect to the performance of the reactor are presented. The internal efficiency in the reactor core is discussed in terms of the following factors:

$$\eta_i = \frac{\left[ \left( 1 - \frac{\Delta p^m}{\sigma^m} \right) \eta_{\tau} - \frac{\tau}{\eta_H} (\sigma^m - 1) \right] K_t}{\delta - \mu \left[ 1 - \left( 1 - \frac{\Delta p^m}{\sigma^m} \right) \eta_{\tau} \right] - (1 - \mu) \tau \left( 1 + \frac{\sigma^m - 1}{\eta_H} \right)}$$

where

$$\Delta p = \frac{p_1 + \Delta p_p + \sigma \Delta p_{p, x}}{p_1}$$

UDC: 621.039.553.3

Card 1/3

L 32922-66

0

$$K_t = \frac{k_r k_{\Delta t}}{k_0} \left[ 0,5 + \sqrt{\frac{0,25}{\sin^2 \frac{\pi}{2} \cdot \frac{H}{e}} + \left( \frac{k_h k_G \bar{c}_p G \tau}{k_{\Delta t} a_n F_p} \right)^2} \right];$$

$$\sigma = \frac{p_3}{p_1};$$

$$\tau = \frac{T_4}{T_1};$$

$$\delta = \frac{T_{cr}^{max}}{T_1};$$

$$\mu = \frac{T_6 - T_5}{T_2 - T_5};$$

and  $\sigma$  is the compression ratio of the cycle;  $\mu$  is the rate of heat recovery;  $p_1$  is the initial gas pressure;  $\Delta p_p$  is the hydraulic resistance of the reactor (including plumbing);  $\Delta p_{p,x}$  is the hydraulic resistance in the heat exchanger and cooler (including plumbing);  $k_r, k_h$  are coefficients of nonuniformity in the radius and height of the reactor, respectively;  $k_G$  is the coefficient of nonuniformity in the gas flow rates in the ducts;  $k_{\Delta t}$  is the coefficient of temperature deviation from

Card 2/3

L 32922-66

ACC NR: AP6018352

the design value for the duct wall;  $H$  is the reactor channel height;  $H_e$  is the equivalent reactor channel height;  $\bar{c}_p$  is the mean specific heat of the gas;  $G_t$  is the total flow rate of the coolant;  $\alpha$  is the heat transfer coefficient of the coolant;  $F_p$  is the total area of fuel element cladding;  $T_w^{\max}$  is the maximum temperature of the cladding wall;  $\eta_t$  is the gas turbine efficiency;  $\eta_k$  is compressor efficiency.  $T_1, T_2, T_4, T_5, T_6, p_4, p_5$  are the absolute temperatures and pressures of specific points in the system.

The authors arrived at the following conclusions:  
 1) With increasing compression ratio  $\sigma$ , the efficiency reaches a maximum at a well defined point, determined by the gas (helium) temperature as a parameter. 2) The increase in rate of heat recovery increases the power plant efficiency and lowers the optimum rate of the compression ratio. 3) Efficiency is only slightly dependent on  $T_w^{\max}$ . 4) The change in the initial gas pressure  $p_1$  has a noticeable effect. 5) An increase in hydraulic resistances  $\Delta p_p$  or  $\Delta p_{p,x}$  reduces efficiency. 6) Intermediate gas cooling during compression substantially changes the parameters of the nuclear gas turbine plant in that it increases efficiency and the compression ratio. The effects of intermediate gas cooling and heating were investigated using a two-stage system in which the gas is passed through the reactor, cooled and compressed twice during each cycle. Based on the experimental data and calculations it appears feasible to attain 50% efficiency using gas at 1000C in such a system. Orig. art. has: 7 figures and 7 formulas.

**ABSTRACT:** The author describes the development of the Sverdlovsk Institute of Mining imeni V.V. Vakhrushev, founded in 1914. The Institute has at present 3,320 students in day courses; 325 persons are trained in senior engineering courses and 230 students in correspondence courses. During 40 years the Institute has turned out more than 9,000 mining engineers. There are 37 chairs and 300 instructors. Together with prominent scientists such as Professors S.A. Volotkovskiy, S.A. Fedorov, A.Ye. Malakhov, A.N. Khodalevich, the Dotsents B.A. Stoylov, A.N. Bredikhin, I.A. Blashkevich, young recently graduated or appointed instructors are working at the Institute, as: Professors A.Ye. Trop, Ya.M. Chernousov, Doctor of Geological Mineralogical Sciences, Dotsents V.I. Shavshukov, A.N. Ikonnikov, S.M. Antonov, I.P. Petrov, etc. These scientific workers take an active part in the development of the mining industry, in the geological investigation of the Urals and in the exploration of eastern areas.

TITLE: Analysis of a high capacity atomic electric power system with conventionally superheated steam

SOURCE: Sverdlovsk. Ural'skiy politekhnicheskiy institut. Trudy, no. 125, 1962. Povysheniye effektivnosti ispol'zovaniya tepla i topliya na teplovykh elektrostantsiyakh (Increasing the efficiency of using heat and fuel in thermal electric power plants), 25-31

TOPIC TAGS: reactor power, boiling water reactor, electric power production

ABSTRACT: Nearly all atomic electric power stations now in operation or being built have low steam parameters preceding the turbine (pressure 15-50 absolute atmospheres, temperature less than 300-375°C), so that the efficiency of the station falls within the 16-30% range. Exceptions are the Beloyarsk installation (90 at abs, 500°C), the Indian Point station with 535°C superheated steam and the Belgian power plant designed for a superheated steam temperature of 565°C. Temperature conditions for the use of high steam parameters may be found from the ex-

Card 1/3

ACCESSION NR: AT5004612

pression for the optimum average temperature of the tharnopower cycle:

$$T_{1c}^{av \text{ opt}} = \sqrt{\frac{T_w^{\max} T_{2c}}{1-z}}$$

where  $T_w^{\max}$  is the maximum (limiting) temperature for the wall of the fuel element shell in °K;  $T_{2c}$  is the condenser temperature in °K and  $z = \eta_t \cdot c_f$  (here  $\eta_t$  is the thermal efficiency of the cycle;  $c_f$  is the fuel component cost of the electric power). When  $c_f$  is low for nuclear fuel (0.0-0.2), high steam parameters will be feasible if the maximum temperature for the shell exceeds 800°C. Since the running cost of nuclear fuel is presently high in most cases and the actual limiting temperature for the fuel element shell is reached at 650-700°C (in the case of ceramic nuclear fuel), it should be assumed that high steam parameters for industrial atomic electric power stations are possible from the standpoint of long-range planning. On this basis, the author reports on the problem of a method for superheating steam to temperatures which are applicable to high pressure turbines (500-600°C). A reactor-turbine unit with an electric power of 100 Mw is studied for a high capacity atomic electric power station with conventionally superheated steam. This

Card 2/3

L 43639-65  
ACCESSION NR: AT5004612

heating method makes it possible to produce high temperature steam, increase the electric power of the station by 20-50% at the same thermal power for the reactor, to reduce the power cost per kw by 15-30% and to produce energy at a cost per kwh on a level with thermal electric power stations. The unit which was studied consisted of a graphite-moderated boiling water reactor, a conventional steam superheater and a VK-100-3 high pressure steam turbine (90 at abs, 535°C). It was found that conventional superheating reduces reactor power requirements by nearly 1.5 times, which lowers the cost of the electric power station since the reactor accounts for 50-70% of the total cost of the station, as well as reducing running costs per kwh for nuclear fuel. Title : The Effect of Morphine and the Character of Glycemic Reaction in the Adrenaline Administration in Experimental Toxic Hepatitis.

Orig; Pub : Latv. PSR Zinatnu Akad. Vestis, Isv. AN LatvSSR, 1956, No 10, 65-68

Abstract : The Study of glycolytic changes in rabbits showed, that morphine increases the adrenaline secretion and does not have a distinct effect on the glycemic reaction in experimental hepatitis, which is characterized by the decrease of glycogen reserves in the liver.
